(Submitted by: Reza Aftabizadeh)

Abstract. We are studying a class of nonlinear nonlocal diffusion problems associated with a $p$-Laplace-type operator, where a nonlocal quantity is present in the diffusion coefficient. We address the issues of existence and uniqueness for the parabolic setting. Then, we study the asymptotic behavior of the solution for large time. For this purpose, we introduce and investigate, in detail, the associated stationary problem. Moreover, since the solutions of the stationary problem are also critical points of some energy functional, we make a classification of its critical points.

1. INTRODUCTION

We consider the problem of finding $u = u(x,t)$ weak solution to

$$
\begin{cases}
    u_t - \nabla \cdot a(\|\nabla u\|^p_p)|\nabla u|^{p-2}\nabla u = f & \text{in } \Omega \times (0,T), \\
    u = 0 & \text{on } \Gamma \times (0,T), \\
    u(\cdot,0) = u_0 & \text{in } \Omega,
\end{cases}
$$

(1.1)

where $\Omega$ is a bounded open set of $\mathbb{R}^n$, $n \geq 1$ with Lipschitz boundary $\Gamma$. We assume

$$
a \text{ is continuous, } a(\xi) > 0, \forall \xi \in \mathbb{R}.
$$

(1.2)

By $|\cdot|_p$, we denote the $L^p(\Omega)$-norm, $1 < p < +\infty$ and we assume

$$
f = f(x) \in W^{-1,q}(\Omega) := (W^{1,p}_0(\Omega))^\ast, \quad u_0 \in W^{1,p}_0(\Omega) \cap L^2(\Omega), \quad \frac{1}{p} + \frac{1}{q} = 1.
$$

(1.3)

For notions on Sobolev spaces, we refer to [5], [15], [16].

During the last decade, many mathematicians have been studying problems associated with the $p$-Laplace operator, which appears in a variety of physical fields (see for instance [1], [2]). In particular, a lot of attention has been devoted to nonlocal problems. One of the justifications of such models...
lies in the fact that in reality the measurements are not made pointwise – but through some local average. Some interesting features of nonlocal problems and more motivation are described in [4], [5], [7], [8], [10] and in the references therein.

The elliptic problems with our type of nonlocality have been studied in [13], [14] and the stability issues for a local case were considered in [3]. Furthermore, the problem (1.1) was examined for \( p = 2 \) in [11] and [12].

We now describe the results obtained in this paper. In Sections 2 and 3, we study the existence and uniqueness of a weak solution of problem (1.1). Next, in Section 4, we investigate the corresponding stationary problem and show that depending on the function \( a \), it can have from a unique up to a continuum of solutions. In particular, since stationary solutions are also critical points of some energy functional (see (2.7)), we prove the existence of its global minimizer.

The main results of this paper are contained in Section 5, where we give the classification of the critical points of the energy functional defined by (2.7), assuming that the function \( a \) satisfies just (1.2) and \( 1 < p < +\infty \).

Finally, in the last section, we study the asymptotic behavior of the solution of problem (1.1) as time goes to infinity. We prove that the solution of problem (1.1) converges to a stationary solution, which is a global minimizer of (2.7), in case of uniqueness of such a stationary point. Moreover, we also present some local stability results for the case of uniqueness of a global minimizer.

2. Existence

**Theorem 2.1.** Let the assumptions above hold and assume that there exist two constants \( \lambda, \Lambda \) such that

\[
0 < \lambda \leq a(\xi) \leq \Lambda, \quad \forall \xi \in \mathbb{R}.
\]  

Then, if \( f \in L^q(\Omega) \subset W^{-1,q}(\Omega) \) for every \( T > 0 \), there exists \( u \), solution to

\[
\begin{align*}
\left\{ \begin{array}{ll}
  u \in L^p(0,T;\W01p(\Omega)) \cap C([0,T];L^r(\Omega)), & r = \min\{2,p\}, \\
  u_t \in L^q(0,T;W^{-1,q}(\Omega)), & u(.,0) = u_0, \\
  \langle u_t, v \rangle + \int_{\Omega} a(\|\nabla u\|_p^p)\|\nabla u\|^{p-2}\nabla u\nabla v dx = \langle f,v \rangle, & \forall v \in W_0^{1,p}(\Omega),
\end{array} \right.
\end{align*}
\]  

where \( \langle \cdot, \cdot \rangle \) denotes the pairing between \( W^{-1,q}(\Omega) \) and \( W^{1,p}(\Omega) \), \( u(t) = u(.,t) \), and \( D'(0,T) \) is the space of distributions on \( (0,T) \).
Proof. We consider $\lambda_1, \ldots, \lambda_n, \ldots$ a basis in $W^{1,p}_0(\Omega) \cap L^2(\Omega)$ consisting of eigenvalues of the problem

$$
\lambda_i \in H_0^s(\Omega), \quad (\lambda_i, v)_{H_0^s(\Omega)} = \mu_i(\lambda_i, v)_{L^2(\Omega)} \quad \forall v \in H_0^s(\Omega),
$$

where $s$ is chosen large enough in such a way that $H_0^s(\Omega) \subset W^{1,p}_0(\Omega)$ continuously. We will suppose the $\lambda_i$’s orthonormal in $L^2(\Omega)$. If $u_0 = \sum_i \beta_i \lambda_i$, then consider

$$
u_n(t) = \sum_{i=1}^n \gamma_i(t) \lambda_i$$

a solution to

$$
\begin{cases}
\int_\Omega u'_n v dx + a(\|\nabla u_n\|_p^p) \int_\Omega |\nabla u_n|^{p-2} \nabla u_n \nabla v dx = \langle f, v \rangle, \\
u_n(0) = \sum_{i=1}^n \beta_i \lambda_i, \quad \forall v \in [\lambda_1, \ldots, \lambda_n],
\end{cases}
$$

(2.3)

where $[\lambda_1, \ldots, \lambda_n]$ is the space spanned by $\lambda_1, \ldots, \lambda_n$. Taking $v = \lambda_j$ and using the fact that the $\lambda_i$’s are orthonormal, we see that (2.3) is equivalent to the Cauchy problem

$$
\gamma'_j(t) = -a \left( \left\| \sum_{i=1}^n \gamma_i(t) \nabla \lambda_i \right\|_p^p \right) \int_\Omega \left\| \sum_{i=1}^n \gamma_i(t) \nabla \lambda_i \right\|^{p-2} \sum_{i=1}^n \gamma_i(t) \nabla \lambda_i \nabla \lambda_j dx + \langle f, \lambda_j \rangle, \\
\gamma_j(0) = \beta_j, \quad \forall j = 1, \ldots, n.
$$

(2.4)

Since the right hand side of the first equation above is continuous in $\gamma_i$, this Cauchy problem possesses a solution. Moreover, using the formulation (2.3) and taking $v = u_n$, we see that

$$
\int_\Omega u'_n u_n dx + a(\|\nabla u_n\|_p^p) \int_\Omega |\nabla u_n|^p dx = \langle f, u_n \rangle,
$$

which implies using (2.1), Poincaré’s and Young’s inequalities

$$
\frac{1}{2} \frac{d}{dt} |u_n|^2 + \lambda \int_\Omega |\nabla u_n|^p dx \leq C |f|_q \|\nabla u_n\|_p \leq \varepsilon \|\nabla u_n\|_p^p + C_\varepsilon |f|^q_q.
$$

Choosing for instance $\varepsilon = \frac{\lambda}{2}$, we arrive to

$$
\frac{1}{2} \frac{d}{dt} |u_n|^2 + \frac{\lambda}{2} \int_\Omega |\nabla u_n|^p dx \leq C_\varepsilon |f|^q_q.
$$

After an integration in $t$, this leads to

$$
\frac{1}{2} |u_n(t)|^2 + \frac{\lambda}{2} \int_0^t \int_\Omega |\nabla u_n|^p dx dt \leq C_\varepsilon \int_0^t |f|^q_q dt + \frac{1}{2} |u_n(0)|^2.
$$

(2.5)
In particular, we see that $|u_n(t)|_2$ remains bounded in time and; thus, the solution to (2.3) or (2.4) is global in time ($|\cdot|_2$ is just a norm in $[\lambda_1, \ldots, \lambda_n]$, where all the norms are equivalent).

Remark that $\|\nabla u_n\|_p$ remains bounded in time uniformly. To see that taking $v = u'_n$ in (2.3), we get

$$\int_\Omega u'_n^2\,dx + a(\|\nabla u_n\|^p) \int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla u'_n\,dx = \langle f, u'_n \rangle. \tag{2.6}$$

Introducing

$$E(u) = \frac{1}{p} A\Big(\int_\Omega |\nabla u|^p\,dx\Big) - \langle f, u \rangle \tag{2.7}$$

with

$$A(z) = \int_0^z a(s)\,ds, \tag{2.8}$$

we see that (2.6) can be written

$$\partial_tE(u_n) = -\int_\Omega u'_n^2\,dx \leq 0. \tag{2.9}$$

Thus, $E(u_n)$ decreases in time and is bounded from above for every $t$. The bound for $\|\nabla u_n\|_p$ follows then from the estimate

$$E(u_n) \geq \frac{\lambda}{p} \|\nabla u_n\|^p - C|f|_q \|\nabla u_n\|_p. \tag{2.10}$$

From (2.5), (2.10), we deduce that

$u_n$ is bounded in $L^p(0, T; W^{1,p}_0(\Omega)) \cap L^\infty(0, T; L^2(\Omega) \cap W^{1,p}_0(\Omega))$.

Furthermore, from the first equation in (2.3), we derive easily if $P_n$ denotes the orthogonal projection from $L^2(\Omega)$ onto $[\lambda_1, \ldots, \lambda_n]$ for every $v \in H^1_0(\Omega)$

$$\int_\Omega u'_n v\,dx = \int_\Omega u'_nP_n(v)\,dx \leq \left(\lambda\left(\int_\Omega |\nabla u_n|^{(p-1)q}\,dx\right)^{\frac{1}{q}} + C|f|_q\right) \|\nabla(P_n v)\|_p$$

$$\leq C\left(\lambda\|\nabla u_n\|^{p-1}_p + |f|_q\right) \|P_n v\|_{H^1_0(\Omega)} \leq C\left(\lambda\|\nabla u_n\|^{p-1}_p + |f|_q\right) \|v\|_{H^1_0(\Omega)}$$

($C$ above denotes various constants independent of $n$). Thus

$$|u'_n|_{H^{-s}(\Omega)} \leq C\left(\lambda\|\nabla u_n\|^{p-1}_p + |f|_q\right),$$

and $u'_n$ is bounded in $L^q(0, T; H^{-s}(\Omega))$. Suppose first $p \geq 2$. Since $W^{1,p}_0(\Omega) \subset L^p(\Omega) \subset H^{-s}(\Omega)$ and since the first embedding is compact (see [15]), we have that $W := \{v \in L^p(0, T; W^{1,p}_0(\Omega)), v \in L^q(0, T; H^{-s}(\Omega))\}$ is compactly embedded in $L^p(0, T; L^p(\Omega)) = L^p(Q_T), Q_T = \Omega \times (0, T)$. Then, we can find a subsequence of $n$ such that $u_n \rightharpoonup u$ in $L^p(0, T; W^{1,p}_0(\Omega))$, and
\[ u_n \to u \text{ in } L^p(0, T; L^p(\Omega)), \quad u_n' \rightharpoonup u' \text{ in } L^q(0, T; H^{-s}(\Omega)), \quad a, \frac{1}{a(\|\nabla u_n\|_p^p)} \to a_\infty \]
in \( L^\infty(0, T) \) - weak*, \( u_n(T) \rightharpoonup u(T) \) in \( L^2(\Omega) \), \( \nabla \cdot |\nabla u_n|^{p-2}\nabla u_n \rightharpoonup \chi \) in \( L^q(0, T; W^{-1,q}(\Omega)) \). In fact,
\[ u_n' \in L^2(0, T; L^2(\Omega)) = L^2(Q_T). \quad (2.11) \]
Indeed, integrating (2.9) from 0 to \( T \), we derive
\[ \int_0^T \int_\Omega |u_n'|^2 \, dx = E(u_n(0)) - E(u_n(T)). \quad (2.12) \]
Using the Young inequality in (2.10), we get
\[ E(u) \geq \frac{\lambda}{p} \|\nabla u\|_p^p - \frac{C|f|_q^q}{\lambda^\frac{q}{p}} - \frac{\lambda}{p} \|\nabla u\|_p^p = -\frac{1}{q} \left( \frac{C|f|_q}{\lambda^\frac{q}{p}} \right)^q, \]
hence, \( E(u_n) \) is bounded from below independently of \( n \). Thus, from (2.12), we obtain (2.11). Therefore, in the case \( 1 < p < 2 \) one has bounds that are independent of \( n \)
\[ u_n \in L^p(0, T; W^{1,p}_0(\Omega)), \quad u_n' \in L^2(0, T; L^2(\Omega)) \subset L^2(0, T; L^p(\Omega)). \]
Hence, by the Aubin-Lions Lemma the embedding of \( \{ v \in L^p(0, T; W^{1,p}_0(\Omega)), \quad v' \in L^2(0, T; L^p(\Omega)) \} \) in \( L^p(0, T; L^p(\Omega)) \) is compact and one can extract a sequence of \( u_n \) satisfying the same convergence as above with \( u_n' \rightharpoonup u' \) in \( L^2(0, T; L^2(\Omega)) \). The fact that \( u \in C([0, T], L^r(\Omega)) \) with \( r = \min\{2, p\} \) follows by the standard argument (see [16]). By rescaling the time in the following way, setting
\[ \alpha(t) = \int_0^t a(\|\nabla u(\cdot, s)\|_p^p) \, ds, \quad (2.13) \]
we reduce solving the problem (1.1) to solving the problem (see [11]):
\[ \begin{align*}
  w_t - \nabla \cdot |\nabla w|^{p-2}\nabla w &= \frac{f}{a(\|\nabla w\|_p^p)} \quad &\text{in } \Omega \times (0, \alpha(T)), \\
  w &= 0 \quad &\text{on } \Gamma \times (0, \alpha(T)), \\
  w(\cdot, 0) &= u_0 \quad &\text{in } \Omega,
\end{align*} \quad (2.14) \]
where \( w(x, \alpha(t)) = u(x, t) \). Replacing in (2.13) \( u \) by \( u_n \), we can also write the first equation of (2.3) as
\[ \int_\Omega u_n' v \, dx + \int_\Omega |\nabla u_n|^{p-2}\nabla u_n \nabla v \, dx = \frac{\langle f, v \rangle}{a(\|\nabla u_n\|_p^p)}. \quad (2.15) \]
Now, passing to the limit in (2.15), one has in the distributional sense in \( Q_T \)
\[ u_t - \chi = a_\infty f \quad (2.16) \]
(therefore, \( u_t \in L^q(0, T; W^{-1,q}(\Omega)) \)). Taking \( v = u_n \) in (2.15), we obtain
\[
\frac{1}{2} \frac{d}{dt} |u_n|^2 + \int_\Omega |\nabla u_n|^p \, dx = \frac{\langle f, u_n \rangle}{a(\|\nabla u_n\|_p^p)}
\]
and by integration on \((0, T)\), we get
\[
\int_{Q_T} |\nabla u_n| \, dx \, dt = \int_0^T \frac{\langle f, u_n \rangle}{a(\|\nabla u_n\|_p^p)} \, dt + \frac{|u_n(0)|^2}{2} - \frac{|u_n(T)|^2}{2}. \tag{2.17}
\]
Since \( u_n \to u \) in \( L^p(Q_T) \), \( \frac{f}{a(\|\nabla u_n\|_p^p)} \rightharpoonup a_{\infty} f \) in \( L^q(Q_T) \) and using the fact that \( \lim_{n \to \infty} |u_n(T)|^2 \geq |u(T)|^2 \) from (2.17), we get
\[
\lim_{n \to \infty} \int_{Q_T} |\nabla u_n|^p \, dx \, dt \leq \int_0^T a_{\infty} \langle f, u \rangle \, dt + \frac{|u_0|^2}{2} - \frac{|u(T)|^2}{2}. \tag{2.18}
\]
Thus, from the inequality
\[
\int_{Q_T} (|\nabla u_n|^{p-2} \nabla u_n - |\nabla v|^{p-2} \nabla v) \cdot \nabla (u_n - v) \, dx \, dt \geq 0,
\]
we derive by taking the \( \overline{\lim} \) for any \( v \in L^p(0, T; W_0^{1,p}(\Omega)) \)
\[
\int_0^T a_{\infty} \langle f, u \rangle \, dt + \frac{|u_0|^2}{2} - \frac{|u(T)|^2}{2} + \int_0^T \langle \chi, v \rangle \, dt - \int_{Q_T} |\nabla v|^{p-2} \nabla v \cdot \nabla (u-v) \, dx \, dt \geq 0. \tag{2.19}
\]
By integrating (2.16) after having multiplied by \( u \), we get
\[
\frac{1}{2} \frac{d}{dt} |u|^2 - \langle \chi, u \rangle = a_{\infty} \langle f, u \rangle
\]
and integrating over \((0, T)\), we obtain
\[
- \int_0^T \langle \chi, u \rangle \, dt = \int_0^T a_{\infty} \langle f, u \rangle \, dt + \frac{|u_0|^2}{2} - \frac{|u(T)|^2}{2}. \tag{2.20}
\]
Thus, combining (2.19), (2.20), we have
\[
\int_0^T (\langle \chi + \nabla \cdot |\nabla v|^{p-2} \nabla v, u - v \rangle \, dt \geq 0 \quad \forall v \in L^p(0, T; W_0^{1,p}(\Omega)).
\]
Taking \( v = u - \delta w, \delta > 0 \), we see
\[
\int_0^T (\langle \chi + \nabla \cdot |\nabla (u - \delta w)|^{p-2} \nabla (u - \delta w), w \rangle \, dt \geq 0 \quad \forall w \in L^p(0, T; W_0^{1,p}(\Omega)).
\]
Letting $\delta \to 0$, we get easily
\[
\int_0^T \langle -\chi + \nabla \cdot |\nabla u|^{p-2}\nabla u, w \rangle \, dt = 0 \quad \forall w \in L^p(0, T; W_0^{1,p}(\Omega))
\]
and the equation (2.16) reads
\[
u_t - \nabla \cdot |\nabla u|^{p-2}\nabla u = a_\infty f.
\]
Going back to (2.18), (2.20), we derive
\[
\lim_{n \to \infty} \int_{Q_T} |\nabla u_n|^p \, dx \, dt \leq \int_{Q_T} |\nabla u|^p \, dx \, dt \leq \lim_{n \to \infty} \int_{Q_T} |\nabla u_n|^p \, dx \, dt
\]
and $\nabla u_n \to \nabla u$ in $L^p(Q_T)$ strongly. Up to a subsequence, we have
\[
\int_\Omega |\nabla (u_n - u)|^p \, dx \, dt \to 0 \quad \text{a.e. } t,
\]
i.e., this implies $\|\nabla u_n\|_p^p \to \|\nabla u\|_p^p$ a.e. $t$ and then $\frac{1}{a(\|\nabla u\|_p^p)} \to a_\infty = \frac{1}{a(\|\nabla u\|_p^p)}$, which completes the proof.

3. Uniqueness

For the reader’s convenience, we start this section by formulating some auxiliary lemmas used throughout the paper.

**Lemma 3.1.** (see [6]) Let $1 < p < +\infty$. There exist positive constants $c_p$, $C_p$ such that for every $\xi, \eta \in \mathbb{R}^n$
\[
c_p N_p(\xi, \eta) \leq |(\xi|^{p-2}\xi - |\eta|^{p-2}\eta) \cdot (\xi - \eta) \leq C_p N_p(\xi, \eta),
\]
where $N_p(\xi, \eta) = \{|\xi| + |\eta|\}^{p-2}|\xi - \eta|^2$, a dot denotes the Euclidean product in $\mathbb{R}^n$.

**Lemma 3.2.** Let $a, b$ be non negative numbers. Then
\[
|a^p - b^p| \leq p|a - b|\{a + b\}^{p-1}.
\]

**Proof.** We can suppose $a > b$. Then
\[
a^p - b^p = \int_0^1 \frac{d}{dt}|b + t(a - b)|^p \, dt = p \int_0^1 |b + t(a - b)|^{p-1} \frac{b + t(a - b)}{|b + t(a - b)|} \cdot (a - b) \, dt \leq p(a - b) \int_0^1 |ta + (1 - t)b|^{p-1} \, dt \leq p(a - b) \int_0^1 \{ |a| + |b| \}^{p-1} \, dt = p|a - b|\{a + b\}^{p-1}.
\]
**Theorem 3.1.** If in addition to the assumptions of Theorem 2.1 for some $L$ it holds that

$$\left| a(\xi) - a(\xi') \right| \leq L|\xi - \xi'| \quad \forall \xi, \xi' \in \mathbb{R}$$

(3.1)

and $f \in L^2(\Omega)$, then the solution to (2.2) is unique.

**Proof.** Let $u_1$, $u_2$ be two weak solutions to

$$\begin{cases}
    u \in L^p(0, T; W_0^{1,p}(\Omega)), & \text{in} \quad u \in L^q(0, T; W^{-1,q}(\Omega)), \\
    u_t - \nabla : |\nabla u|^{p-2}\nabla u = f, & \text{in} \quad \frac{1}{a(\|\nabla u\|_p^p)}.
\end{cases}$$

(3.2)

By subtraction, we obtain

$$(u_1 - u_2)_t - \nabla \cdot (|\nabla u_1|^{p-2}\nabla u_1 - |\nabla u_2|^{p-2}\nabla u_2) = \left(\frac{1}{a(\|\nabla u_1\|_p^p)} - \frac{1}{a(\|\nabla u_2\|_p^p)}\right) f.$$  

Multiplying by $u_1 - u_2$, integrating over $\Omega$ and using (2.1), (3.1), we get

$$\frac{1}{2} \frac{d}{dt} \left| u_1 - u_2 \right|_2^2 + \int_\Omega \left( |\nabla u_1|^{p-2}\nabla u_1 - |\nabla u_2|^{p-2}\nabla u_2 \right) \cdot \nabla (u_1 - u_2) \, dx$$

$$\leq \frac{L}{\lambda^2} \left( \|\nabla u_1\|_p^p - \|\nabla u_2\|_p^p \right) \int_\Omega f(u_1 - u_2) \, dx.$$  

(3.3)

From Lemma 3.2 and the H"older inequality, we derive

$$\left| \|\nabla u_1\|_p^p - \|\nabla u_2\|_p^p \right| = \left| \int_\Omega (|\nabla u_1|^{p} - |\nabla u_2|^{p}) \, dx \right| \leq \int_\Omega \left| \|\nabla u_1\|_p^{p} - \|\nabla u_2\|_p^{p} \right| \, dx$$

$$\leq p \int_\Omega \left( |\nabla u_1| + |\nabla u_2| \right)^{p-1} |\nabla (u_1 - u_2)| \, dx$$

(3.4)

$$= p \int_\Omega \left( |\nabla u_1| + |\nabla u_2| \right)^{\frac{p}{2}} \left( |\nabla u_1| + |\nabla u_2| \right)^{\frac{p}{2}-1} |\nabla (u_1 - u_2)| \, dx$$

$$\leq p \left( \int_\Omega (|\nabla u_1| + |\nabla u_2|)^p \, dx \right)^{\frac{1}{2}} \left( \int_\Omega (|\nabla u_1| + |\nabla u_2|)^{p-2} |\nabla (u_1 - u_2)|^2 \, dx \right)^{\frac{1}{2}}.$$  

From Lemma 3.1, we obtain

$$\int_\Omega (|\nabla u_1|^{p-2}\nabla u_1 - |\nabla u_2|^{p-2}\nabla u_2) \cdot \nabla (u_1 - u_2) \, dx$$

$$\geq c_p \int_\Omega \left( |\nabla u_1| + |\nabla u_2| \right)^{p-2} |\nabla (u_1 - u_2)|^2 \, dx.$$  

Combining (3.3) and the two inequalities above leads to

$$\frac{1}{2} \frac{d}{dt} |u_1 - u_2|_2^2 + c_p \int_\Omega \left( |\nabla u_1| + |\nabla u_2| \right)^{p-2} |\nabla (u_1 - u_2)|^2 \, dx$$
Nonlocal $p$-Laplace Equations

\[
\leq \frac{Lp}{\lambda^2} \left| \int_{\Omega} f(u_1 - u_2) dx \right| \left( \int_{\Omega} (|\nabla u_1| + |\nabla u_2|)^p dx \right)^{\frac{1}{2}} \times \left( \int_{\Omega} (|\nabla u_1| + |\nabla u_2|)^p - 2 |\nabla (u_1 - u_2)|^2 dx \right)^{\frac{1}{2}} \leq \frac{c_p}{2} \int_{\Omega} (|\nabla u_1| + |\nabla u_2|)^{p-2} |\nabla (u_1 - u_2)|^2 dx + C(t) \int_{\Omega} |u_1 - u_2|^2 dx.
\]

(In the last inequality above, we use Young’s inequality. Note that $C \in L^1(0, T)$). Therefore, we have

\[
\frac{1}{2} \frac{d}{dt} |u_1 - u_2|^2_2 \leq C(t) \int_{\Omega} |u_1 - u_2|^2 dx.
\]

The uniqueness follows then from Gronwall’s inequality. □

**Theorem 3.2.** Let the assumptions (1.2), (1.3) hold and, in addition, the function $a$ is such that

\[
s \mapsto a(s^p) s^{p-1} \text{ is nondecreasing,}
\]

then the solution to (2.2) is unique.

**Proof.** Let $u_1, u_2$ be two solutions to (2.2), then taking $v = u_1 - u_2$ and by subtraction, one has

\[
\frac{1}{2} \frac{d}{dt} |u_1 - u_2|^2_2 + \int_{\Omega} \left( a(\|\nabla u_1\|^p_p) |\nabla u_1|^{p-2} \nabla u_1 - a(\|\nabla u_2\|^p_p) |\nabla u_2|^{p-2} \nabla u_2 \right) \nabla (u_1 - u_2) dx = 0. \tag{3.6}
\]

By expanding the integral term $I$, one gets

\[
I = \int_{\Omega} \left( a(\|\nabla u_1\|^p_p) |\nabla u_1|^{p-2} \nabla u_1 |\nabla u_2|^{p-2} \nabla u_2 - a(\|\nabla u_2\|^p_p) |\nabla u_2|^{p-2} \nabla u_2 |\nabla u_1|^{p-2} \nabla u_1 \right) dx.
\]

Recall that $a(\|\nabla u_i\|^p_p), i = 1, 2$ are independent of $x$ and can be pulled out of the integrals. Using Hölder’s inequality, we see

\[
\int_{\Omega} |\nabla u_1|^{p-2} \nabla u_1 |\nabla u_2|^{p-2} \nabla u_2 dx \leq \|\nabla u_2\|^p_p \|\nabla u_1\|^{p-1}_p,
\]

\[
\int_{\Omega} |\nabla u_2|^{p-2} \nabla u_2 |\nabla u_1|^{p-2} \nabla u_1 dx \leq \|\nabla u_1\|^p_p \|\nabla u_2\|^{p-1}_p.
\]

Then using (3.5), we get
I ≥ a(∥∇u∥_p^p) \left( ∥∇u∥_p^p - ∥∇u∥_p^{p-1} ∥∇u∥_p \right)
+ a(∥∇u∥_p^p) \left( ∥∇u∥_p^p - ∥∇u∥_p^{p-1} ∥∇u∥_p \right)
= \left( a(∥∇u∥_p^p) ∥∇u∥_p^{p-1} - a(∥∇u∥_p^p) ∥∇u∥_p^{p-1} ∥∇u∥_p \right) (∥∇u∥_p^p - ∥∇u∥_p^p) ≥ 0.

Hence, (3.6) implies \( \frac{d}{dt} |u_1 - u_2|^2 \leq 0 \), and; therefore, the result follows. □

**Remark 3.1.** Note that (3.5) holds in particular for a nondecreasing.

### 4. The stationary problem

In this section, we consider the associated stationary problem to the problem (1.1), that is, the following problem

\[
\begin{align*}
\begin{cases}
- \nabla \cdot a(∥∇u∥_p^p)|∇u|^{p-2} ∇u = f & \text{in } Ω, \\
u = 0 & \text{on } Γ.
\end{cases}
\end{align*}
\]

(4.1)

We will assume here that \( f ∈ W^{-1,q}(Ω) \). In a weak form, \( u \) is a weak solution to

\[
\begin{align*}
\begin{cases}
u ∈ W^{1,p}_0(Ω), \\
∫_Ω a(∥∇u∥_p^p)|∇u|^{p-2} ∇u ∇v dx = \langle f,v \rangle & ∀v ∈ W^{1,p}_0(Ω).
\end{cases}
\end{align*}
\]

(4.2)

In order to solve the stationary problem, we introduce \( ϕ \) the solution to

\[
\begin{align*}
\begin{cases}
ϕ ∈ W^{1,p}_0(Ω), \\
∫_Ω |∇ϕ|^{p-2} ∇ϕ ∇v dx = \langle f,v \rangle & ∀v ∈ W^{1,p}_0(Ω).
\end{cases}
\end{align*}
\]

(4.3)

It is known that for \( f ∈ W^{-1,q}(Ω) \), (4.3) admits a unique solution [6].

**Theorem 4.1.** Suppose that (1.2) holds, \( 1 < p < +∞ \). Then for \( f ∈ W^{-1,q}(Ω) \), the mapping \( u \mapsto ∥∇u∥_p^p \) is one-to-one mapping from the set of solutions to (4.2) onto the set of solutions in \( \mathbb{R} \) of the equation

\[
a(µ)^{\frac{p}{p-1}} µ = ∥∇ϕ∥_p^p.
\]

(4.4)

**Proof.** Let \( u \) be a solution to the stationary problem, then

\[
∫_Ω a(∥∇u∥_p^p)|∇u|^{p-2} ∇u ∇v dx = \langle f,v \rangle
\]

\[
= ∫_Ω |∇ϕ|^{p-2} ∇ϕ ∇v dx \quad ∀v ∈ W^{1,p}_0(Ω),
\]

(4.5)
which implies
\[ a(\|\nabla u\|_p^p)^{\frac{1}{p-1}} u = \varphi, \]  
(4.6)
from where follows
\[ a(\|\nabla u\|_p^p)^{\frac{1}{p-1}} \|\nabla u\|_p^p = \|\nabla \varphi\|_p^p. \]  
(4.7)
Hence, \(\|\nabla u\|_p^p\) is a solution to (4.4).

Now, let \(\mu\) be a solution to (4.4), \(u\) denotes the solution to
\[ u \in W_0^{1,p}(\Omega), \quad \int_{\Omega} a(\mu) |\nabla u|^{p-2} \nabla u \nabla v dx = \langle f, v \rangle \quad \forall v \in W_0^{1,p}(\Omega), \]  
(4.8)
then \(a(\mu)^{\frac{1}{p-1}} u = \varphi\). Therefore, we get
\[ a(\mu)^{\frac{1}{p-1}} \|\nabla u\|_p^p = \|\nabla \varphi\|_p^p = a(\mu)^{\frac{1}{p-1}} \mu \Rightarrow \|\nabla u\|_p^p = \mu \]
and \(u\) is a solution to (4.2). Now to show the injectivity, we have
\[ \|\nabla u_1\|_p^p = \|\nabla u_2\|_p^p \Rightarrow a(\|\nabla u_1\|_p^p) = a(\|\nabla u_2\|_p^p) \Rightarrow u_1 = u_2, \]
due to the uniqueness of the solution of (4.8).

\[ \square \]

**Remark 4.1.** The stationary points are determined by the solutions to
\[ a(\mu) = \|\nabla \varphi\|_p^{p-1} \mu^{\frac{1}{p-1}}. \]  
(4.9)
Thus, it can happen that there is one solution, several, infinitely many solutions or no solution (just in the case where \(a\) is not bounded away from 0). It depends on the function \(a\), see Figure 1. In the case where (3.5) holds, the set of stationary points is an interval, which is reduced to a point when \(a(s^p)s^{p-1}\) is increasing.

The solutions of the problem (4.2) can be also found as critical points of the energy \(E(u)\), defined by (2.7), (2.8) and
\[ E'(u) = -\nabla \cdot a(\|\nabla u\|_p^p) |\nabla u|^{p-2} \nabla u - f. \]  
(4.10)
If \(u_\infty\) is a critical point of \(E\) on \(W_0^{1,p}(\Omega)\), then \(u_\infty\) is a solution to (4.2). Indeed, if \(u_\infty\) is a critical point, then for arbitrary \(v \in W_0^{1,p}(\Omega)\), it holds
\[ \frac{d}{d\delta} E(u_\infty + \delta v) \bigg|_{\delta=0} = a(\|\nabla u_\infty\|_p^p) \int_\Omega |\nabla u_\infty|^{p-2} \nabla u_\infty \nabla v - \langle f, v \rangle = 0. \]
Thus, \(u_\infty\) is a solution to (4.2) and a stationary point.

**Theorem 4.2.** Let (2.1) hold, \(f \in W^{-1,q}(\Omega)\), then \(E(u)\) admits a global minimizer on \(W_0^{1,p}(\Omega)\).
Proof. To prove this theorem, we will use the direct method of calculus of variations. We claim that $E$ is coercive and bounded from below. Indeed, Hölder’s and Poincaré’s inequalities imply $|\langle f, u \rangle| \leq |f|_1 |\nabla u|_p$, therefore,

$$E(u) = \frac{1}{p} A(\|\nabla u\|_p^p) - \langle f, u \rangle \geq \frac{\lambda}{p} \|\nabla u\|_p^p - |f|_1 |\nabla u|_p.$$  \quad (4.11)

Since $p > 1$, the coerciveness follows. Now coming back to (4.11) and using Young’s inequality, we obtain

$$E(u) \geq \frac{\lambda}{p} \|\nabla u\|_p^p - \frac{(|f|_1)^q}{\lambda^q} - \frac{\lambda}{p} \|\nabla u\|_p^p = -\frac{1}{q} \left( \frac{|f|_1}{\lambda^\frac{1}{q}} \right)^q. \quad (4.12)$$

Thus, $E$ is also bounded from below.

Let $u_n \in W^{1,p}_0(\Omega)$ be a minimizing sequence of $E$. From (4.11), it follows that $u_n$ is bounded in $W^{1,p}_0(\Omega)$. Hence, for some $u_\infty \in W^{1,p}_0(\Omega)$, we have $u_n \rightharpoonup u_\infty$ in $W^{1,p}_0(\Omega)$. Next, we show that $E$ is weakly lower semicontinuous.
on $W^{1,p}_0(\Omega)$. In fact, it holds that
\[
\lim_{n \to \infty} \|\nabla u_n\|_p^p \geq \|\nabla u_\infty\|_p^p
\]
(the norm is weakly lower semicontinuous). Considering a subsequence $u_{n_k}$ such that
\[
\lim_{n \to \infty} \|\nabla u_n\|_p^p = \lim_{k \to \infty} \|\nabla u_{n_k}\|_p^p
\]
and due to the fact that $u_{n_k}$ is a minimizing sequence, we see
\[
\inf_{W^{1,p}_0(\Omega)} E(u) = \lim_{k \to \infty} E(u_{n_k}) = 1
\]
which implies $u_\infty$ is a minimizer of $E$ on $W^{1,p}_0(\Omega)$. Therefore, the result follows. □

Note that the minimizer might be not unique.

5. Remarks on the stationary points

First, suppose that, we are in case of Figure 2, then we have:

**Theorem 5.1.** Let $u_1$ be the stationary point corresponding to $\mu_1$ such that
\[
a(\mu) < \|\nabla \varphi\|_p^{p-1} \mu_1^{\frac{1}{p}-1} \quad \forall \mu \in (\mu, \mu_1),
\]
\[
a(\mu) > \|\nabla \varphi\|_p^{p-1} \mu_1^{\frac{1}{p}-1} \quad \forall \mu \in (\mu_1, \overline{\mu}).
\]
Then $u_1$ is a local minimizer for $E$. More precisely, one has $E(u_1) < E(u)$ \(\forall u \neq u_1, \|\nabla u\|_p^p \in (\mu, \overline{\mu})\).

**Proof.** Recall that by Theorem 4.1, we have that
\[
\mu_1 = \|\nabla u_1\|_p^p, \quad u_1 = \frac{\varphi}{a(\mu_1)^{\frac{1}{p}-1}}.
\]

(i) Suppose $\|\nabla u\|_p^p > \mu_1$. Then from (2.7), (5.2), we have
\[
E(u) - E(u_1) = \frac{1}{p} \|\nabla u\|_p^p \int_0^{\|\nabla u\|_p^p} a(s)ds - \langle f, u \rangle + \langle f, u_1 \rangle
\]
\[
> \frac{1}{p} \|\nabla \varphi\|_p^{p-1} \int_0^{\|\nabla u\|_p^p} s^{\frac{1}{p}-1}ds - \langle f, u \rangle + \langle f, u_1 \rangle
\]
\[
= \|\nabla \varphi\|_p^{p-1}\|\nabla u\|_p - \|\nabla \varphi\|_p^{p-1}\|\nabla u_1\|_p - \langle f, u \rangle + \langle f, u_1 \rangle.
\]
From (4.3) and using Hölder’s inequality, we see

\[ |\langle f, u \rangle| = \left| \int_\Omega |\nabla \varphi|^{p-2} \nabla \varphi \nabla u dx \right| \leq \left( \int_\Omega |\nabla u|^p dx \right)^{\frac{1}{p}} \left( \int_\Omega |\nabla \varphi|^{q(p-1)} dx \right)^{\frac{1}{q}} = \|\nabla u\|_p \|\nabla \varphi\|_p^{p-1}, \tag{5.5} \]

where \( q = \frac{p}{p-1} \). Now, by (4.4) and (5.3), we obtain

\[ \langle f, u_1 \rangle = \int_\Omega |\nabla \varphi|^{p-2} \nabla \varphi \nabla u_1 dx \]

\[ = \int_\Omega |\nabla \varphi|^{p-2} \nabla \varphi \frac{\nabla \varphi}{a(\mu_1)^{\frac{1}{p-1}}} dx = \|\nabla \varphi\|_p \|\nabla u_1\|_p = \|\nabla \varphi\|_p^{p-1} \|\nabla u_1\|_p. \tag{5.6} \]

Hence, combining (5.4) – (5.6), we derive \( E(u) > E(u_1) \) for \( \|\nabla u\|_p > \mu_1 \).

(ii) Suppose now \( \|\nabla u\|_p < \mu_1 \). Therefore, as above, we get

\[ E(u) - E(u_1) = -\frac{1}{p} \int_0^\|\nabla u\|_p^p a(s) ds - \langle f, u \rangle + \langle f, u_1 \rangle, \]

and by (5.1), (5.5), (5.6), we can conclude

\[ E(u) - E(u_1) > -\frac{1}{p} \|\nabla \varphi\|_p^{p-1} \int_\|\nabla u\|_p^{p-1} s^{p-1} ds - \langle f, u \rangle + \langle f, u_1 \rangle \]
\[ E(u) > E(u_1) \text{ for } \|\nabla u\|_p \in (\mu, \mu_1), u \neq u_1. \]

\textbf{Remark 5.1.} If \( u \neq u_1 \), one does not have necessarily \( \|\nabla u\|_p \neq \|\nabla u_1\|_p = \mu_1 \) and the proof of the theorem is incomplete. However, if \( \|\nabla u\|_p = \|\nabla u_1\|_p \), one has (see above) \( 0 \leq E(u) - E(u_1) = \langle f, u - u_1 \rangle \). If this last quantity is vanishing, we will show in Lemma 5.2 that \( u = u_1 \).

\textbf{Remark 5.2.} If one assumes
\[
a(\mu) < \|\nabla \varphi\|_p^{p-1} \mu^{\frac{1}{p} - 1} \quad \forall \mu \geq \mu_1.
\]

Then, one gets only \( E(u) \geq E(u_1) \). Thus, \( E \) can possess infinitely many global minimizers (see Figure 1d).

\textbf{Lemma 5.1.} Let \( u_2 \) be the stationary point corresponding to \( \mu_2 \) such that
\[
a(\mu) > \|\nabla \varphi\|_p^{p-1} \mu^{\frac{1}{p} - 1} \quad \forall \mu \in (\mu_1, \mu_2),
\]
\[
a(\mu) < \|\nabla \varphi\|_p^{p-1} \mu^{\frac{1}{p} - 1} \quad \forall \mu \in (\mu_2, \mu_3)
\]
(see Figure 3). Then \( u_2 \) is a point of local maximum for \( E \) in the direction of \( \varphi \) where \( \varphi \) is the solution of the problem (4.3). More precisely, one has \( E(u_2) > E(u_2 + \delta \varphi), \) for every \( \delta \neq 0 \) such that
\[
\delta \geq -\frac{1}{a(\mu_2)^{\frac{1}{p} - 1}}, \quad \|\nabla (u_2 + \delta \varphi)\|_p \in (\mu_1, \mu_3).
\]

\textbf{Proof.} As above by Theorem 4.1, we have that
\[
\mu_2 = \|\nabla u_2\|_p^p, \quad u_2 = \frac{\varphi}{a(\mu_2)^{\frac{1}{p} - 1}}.
\]
(i) Let us first assume that \( \|\nabla (u_2 + \delta \varphi)\|_p^p > \mu_2 \). Then from (2.7), (4.3), (5.9), we have
\[
E(u_2 + \delta \varphi) - E(u_2) = \frac{1}{p} \int_{\|\nabla u_2\|_p^p}^{|\nabla (u_2 + \delta \varphi)|_p^p} a(s) ds - \delta \langle f, \varphi \rangle
\]
\[
< \frac{1}{p} \|\nabla \varphi\|_p^{p-1} \int_{\|\nabla u_2\|_p^p}^{|\nabla (u_2 + \delta \varphi)|_p^p} s^{\frac{1}{p} - 1} ds - \delta \|\nabla \varphi\|_p^p
\]
\[
= \|\nabla \varphi\|_p^{p-1} (\|\nabla (u_2 + \delta \varphi)\|_p - \|\nabla u_2\|_p) - \delta \|\nabla \varphi\|_p^p
\]
\[ y = \| \nabla \varphi \|_p^{p-1} \mu^{\frac{1}{p}-1} \]

\[ y = a(\mu) \]

\[ \mu \]

\[ \mu_2 \]

\[ \bar{\mu} \]

Figure 3

\[ = \| \nabla \varphi \|_p^{p-1} \left( \frac{1}{a(\mu_2)^{\frac{1}{p-1}}} + \delta \| \nabla \varphi \|_p - \frac{\| \nabla \varphi \|_p}{a(\mu_2)^{\frac{1}{p-1}}} \right) - \delta \| \nabla \varphi \|_p = 0, \quad (5.11) \]

if \( \frac{1}{a(\mu_2)^{\frac{1}{p-1}}} + \delta \geq 0 \). Thus, it holds that

\[ E(u_2 + \delta \varphi) < E(u_2) \quad \text{for} \quad \| \nabla(u_2 + \delta \varphi) \|_p > \mu_2. \]

(ii) Suppose now \( \| \nabla(u_2 + \delta \varphi) \|_p < \mu_2 \). Then similarly, from (2.7), (4.3), (5.8), we get

\[ E(u_2 + \delta \varphi) - E(u_2) = -\frac{1}{p} \int \| \nabla u_2 \|_p^p a(s) ds - \delta \langle f, \varphi \rangle \]

\[ \quad < -\| \nabla \varphi \|_p^{p-1} (\| \nabla u_2 \|_p - \| \nabla(u_2 + \delta \varphi) \|_p) - \delta \| \nabla \varphi \|_p^p = 0 \quad (5.12) \]

as in part (i). Hence,

\[ E(u_2 + \delta \varphi) < E(u_2) \quad \text{for} \quad \| \nabla(u_2 + \delta \varphi) \|_p < \mu_2. \]

\[ \Box \]

**Lemma 5.2.** Let \( u \) be a solution to the problem (4.2). Suppose that (1.2) holds and that \( \psi \in W_0^{1,p}(\Omega) \), \( \psi \neq 0 \) is such that

\[ \langle f, \psi \rangle = 0. \quad (5.13) \]

Then

\[ E(u + \psi) > E(u), \quad (5.14) \]
i.e., \( u \) is a point of minimum for \( E \) in any direction of the hyperplane defined by (5.13).

**Proof.** Let us consider \( \psi \), which satisfies (5.13). Then for \( \| \nabla (u + \psi) \|_p > \| \nabla u \|_p \) from (2.1), we have

\[
E(u + \psi) - E(u) = \frac{1}{p} \int_0^1 \frac{\| \nabla (u + s\psi) \|_p^p}{\| \nabla u \|_p^p} a(s)ds > 0.
\]

Hence, it remains to prove that \( \| \nabla (u + \psi) \|_p > \| \nabla u \|_p \). Due to (5.13) and since \( a > 0 \), we get

\[
\int_\Omega |\nabla u|^{p-2} \nabla u \nabla \psi dx = 0.
\]

Then, we see

\[
\| \nabla (u + \psi) \|_p^p - \| \nabla u \|_p^p = \int_0^1 \frac{d}{ds} \int_\Omega |\nabla (u + s\psi)|^p dx ds
\]

\[
= p \int_0^1 \int_\Omega (| \nabla (u + s\psi) |^{p-2} \nabla (u + s\psi) \nabla \psi dx ds
\]

\[
= p \int_0^1 \int_\Omega (| \nabla (u + s\psi) |^{p-2} \nabla (u + s\psi) - | \nabla u |^{p-2} \nabla u) \nabla \psi dx ds.
\]

From Lemma 3.1, we have

\[
(\| \nabla (u + s\psi) \|^{p-2} \nabla (u + s\psi) - | \nabla u |^{p-2} \nabla u) \nabla (s\psi)
\]

\[
\geq c_p (| \nabla (u + s\psi) | + | \nabla u |)^{p-2} | \nabla (s\psi) |^2.
\]

This shows that \( \| \nabla (u + \psi) \|_p - \| \nabla u \|_p \geq 0 \). If the equality holds, then

\[
(\| \nabla (u + s\psi) | + | \nabla u |)^{p-2} | \nabla \psi |^2 = 0 \quad \text{a.e. } x \in \Omega, \ s \in (0, 1).
\]

This implies that for \( | \nabla u | = 0 \), we have \( | \nabla \psi | = 0 \) and for \( | \nabla u | \neq 0 \) as well.

Thus, \( \psi = 0 \), which contradicts our assumptions. This completes the proof of the theorem. \( \square \)

**Theorem 5.2.** Let \( f \neq 0, (1.2) \) hold, \( u_2 \) be a solution to (4.2) such that (5.8), (5.9) hold (see Figure 3, \( u_2 \) corresponds to \( \mu_2 \)). Then \( u_2 \) is a saddle point for the energy (2.7).

**Proof.** The statement of the theorem is a consequence of Lemmas 5.1 and 5.2. \( \square \)

**Remark 5.3.** The same situation occurs if the graph of \( a \) is not crossing the graph of \( y \) and touching it (see Figure 4).
Theorem 5.3. Let $u^*$ be a solution of the problem (4.2) corresponding to the solutions $\mu^*$ of the equation (4.4). Let
\[ y(s) = \|\nabla \varphi\|_{p}^{p-1} s^{\frac{1}{p}-1}, \tag{5.15} \]
then one has
\[ E(u^*) = \frac{1}{p} \int_{0}^{\mu^*} (a(s) - y(s)) ds. \]

Proof. From (2.7), one has
\[ E(u^*) = \frac{1}{p} \int_{0}^{\mu^*} \|\nabla u^*\|_{p}^{p} a(s) ds - \langle f, u^* \rangle. \]
Due to the definition of $u^*$ (see (5.3)), we get
\[ \frac{1}{p} \int_{0}^{\mu^*} y(s) ds = \frac{1}{p} \|\nabla \varphi\|_{p}^{p-1} \int_{0}^{\mu^*} \|\nabla u^*\|_{p}^{p} s^{\frac{1}{p}-1} ds = \|\nabla \varphi\|_{p}^{p-1} \|\nabla u^*\|_{p} = \langle f, u^* \rangle. \]
(see (5.6)). Hence, the result follows. \hfill \Box

Corollary 5.1. Let $u_1, u_2$ be two solutions of the problem (4.2) corresponding to the solutions $\mu_1 < \mu_2$ of the equation (4.4), respectively. Then one has
\[ E(u_1) - E(u_2) = -\frac{1}{p} \int_{\mu_1}^{\mu_2} (a(s) - y(s)) ds = -\frac{1}{p} A_{12} \tag{5.16} \]
and
\[ A_{12} > 0 \Rightarrow E(u_1) < E(u_2); \]
\[ A_{12} < 0 \Rightarrow E(u_2) < E(u_1); \]
\[ A_{12} = 0 \Rightarrow E(u_1) = E(u_2). \]

**Corollary 5.2.** Let \( u_1 \) and \( u_2 \) be two solutions of the problem (4.2) corresponding to the solutions \( \mu_1 < \mu_2 \) of the equation (4.4). If we assume that
\[
\begin{align*}
 a(\mu) > y(\mu) \quad &\text{for} \quad \mu_1 < \mu < \mu_2 \\
 &\text{(resp.} \quad a(\mu) < y(\mu), \quad a(\mu) = y(\mu)),
\end{align*}
\]
then
\[ E(u_1) < E(u_2) \quad (\text{resp.} \quad E(u_1) > E(u_2), \quad E(u_1) = E(u_2)). \]

**Corollary 5.3.** The absolute minimum of \( E \) corresponds to a point \( \mu_\infty \) such that
\[
\begin{align*}
\int_{\mu}^{\mu_\infty} (a(s) - y(s))ds &\geq 0, \quad \forall \mu > \mu_\infty, \quad \mu \text{ corresponding to a stationary point}, \\
\int_{\mu}^{\mu_\infty} (a(s) - y(s))ds &\leq 0, \quad \forall \mu < \mu_\infty, \quad \mu \text{ corresponding to a stationary point}.
\end{align*}
\]

Therefore, due to Theorem 5.3 and its corollaries, we can compare the energy at any two different stationary points and we can find a global minimizer of the energy \( E(u) \).

**Example 5.1.** Let \( u_i, \ i = 1, 2, 3 \) be solutions of the problem (4.2) corresponding to the solutions \( \mu_i, \ i = 1, 2, 3 \) of the equation (4.4) such as on Figure 5. Then by Corollary 5.2, we get that \( E(u_1) < E(u_2), E(u_3) < E(u_2) \). It is left to compare the energy at the points \( u_1 \) and \( u_3 \). By Corollary 5.1, we see that
\[ E(u_1) - E(u_3) = -\frac{1}{p} A_{13} = -\frac{1}{p} (|A_{12}| - |A_{23}|) < 0, \]
where
\[ A_{ij} := \int_{\mu_i}^{\mu_j} (a(s) - y(s))ds, \quad i = 1, 2, \quad j = 2, 3. \]

Hence, \( u_1 \) is a global minimizer of the energy \( E(u) \) defined by (2.7).

**Remark 5.4.** We label the solutions to (4.4) as \( \mu_1 < \mu_2 < \ldots < \mu_N \) with the convention that we choose only one point \( \mu_i \) in the interval \( (\mu_i, \overline{\mu_i}) \), when the solutions consist of one interval \( (\mu_i, \overline{\mu_i}) \) (see Figure 6). We denote by \( \{u\}_1, \{u\}_2, \ldots, \{u\}_N \) the sets of solutions of (4.2), corresponding to \( \mu_1 < \mu_2 < \ldots < \mu_N \) solutions of (4.4). Then due to our convention, we see that \( \{u\}_i \) can consist of one point or infinitely many points.
By Corollary 5.2 for arbitrary $u \in \{u_i\}_i$, $i \in I := \{1, \ldots, N\}$, it holds that $E(u) = E_i$, $i \in I$. Therefore, in the case when the stationary problem (4.2) is having infinitely many solutions, the energy (2.7) can have a unique, several or infinitely many global minimizers.
We start with a lemma:

**Lemma 6.1.** Let $u$ be a weak solution to (1.1) and suppose that (2.1) holds. There exists a sequence $t_k$ such that $u_k = u(\cdot, t_k) \to u_\infty$ in $W^{1,p}_0(\Omega)$ as $t_k \to +\infty$, where $u_\infty$ is a stationary point.

**Proof.** Taking $v = u_t$ in (2.2), we obtain

$$a(||\nabla u||_p^p) \int_\Omega |\nabla u|^{p-2} \nabla u \nabla u_t dx - \langle f, u_t \rangle = -|\partial_t u|^2;$$

$$\partial_t E(u) = -|\partial_t u|^2 \leq 0.$$  

Hence, $E(u(t)) \leq E(u_0)$ and $E(u(t))$ decreases with the time. Remark that from (4.11), we have that $||\nabla u||_p^p$ is uniformly bounded in $t$. Since $E$ is also bounded from below (see (4.12)), then it follows

$$E(u(t)) \to E_\infty$$  

($E_\infty$ is some constant). From above, we get

$$E(u(t)) - E(u(s)) = -\int_s^t |\partial_t u|^2_2(\xi) d\xi, \quad \int_s^\infty |\partial_t u|^2_2(\xi) d\xi < +\infty,$$

which implies for a sequence $t_k$ that $\partial_t u(\cdot, t_k) \to 0$ in $L^2(\Omega)$. From the equation in (2.2) with $u_k = u(\cdot, t_k)$, we obtain

$$\int_\Omega \partial_t u(\cdot, t_k) u_k dx + a(||\nabla u_k||_p^p) \int_\Omega |\nabla u_k|^p dx = \langle f, u_k \rangle.$$  

(6.2)

We can show as in (2.5) that $|u(t)|_2^2 \leq C$. Up to a subsequence, it holds that $u(\cdot, t_k) = u_k \to u_\infty$ in $W^{1,p}_0(\Omega)$, $u_k \to u_\infty$ in $L^2(\Omega)$, $||\nabla u_k||_p^p \to l_\infty$, $g_k = |\nabla u_k|^{p-2} \nabla u_k \to g_\infty$ in $(L^q(\Omega))^n$. Passing to the limit in (6.2), we see

$$a(l_\infty l_\infty) = \langle f, u_\infty \rangle.$$  

(6.3)

Next, taking $v \in W^{1,p}_0(\Omega) \cap L^2(\Omega)$, we get

$$\int_\Omega \partial_t u(\cdot, t_k) v dx + a(||\nabla u_k||_p^p) \int_\Omega |\nabla u_k|^{p-2} \nabla u_k \nabla v dx = \langle f, v \rangle.$$  

Passing to the limit, we derive

$$a(l_\infty) \int_\Omega g_\infty \nabla v dx = \langle f, v \rangle.$$  

(6.4)
Since $a > 0$ combining (6.3), (6.4), we can conclude that

$$l_\infty = \int_\Omega g_\infty \nabla u_\infty dx.$$

We claim that $u_k \to u_\infty$ strongly in $W^{1,p}_0(\Omega)$. Indeed, for $p \geq 2$, there exists a constant $C_p > 0$ such that

$$\chi_k = \int_\Omega (|\nabla u_k|^{p-2}\nabla u_k - |\nabla u_\infty|^{p-2}\nabla u_\infty) \nabla (u_k - u_\infty)dx \geq C_p \int_\Omega |\nabla (u_k - u_\infty)|^p dx.$$

Developing

$$\chi_k = \int_\Omega |\nabla u_k|^p dx - \int_\Omega g_k \nabla u_\infty dx - \int_\Omega |\nabla u_\infty|^{p-2}\nabla u_\infty \nabla u_k dx + \int_\Omega |\nabla u_\infty|^p dx$$

$$\to l_\infty - \int_\Omega g_\infty \nabla u_\infty dx - \int_\Omega |\nabla u_\infty|^p dx + \int_\Omega |\nabla u_\infty|^p dx = 0.$$

This implies

$$l_\infty = \lim_k \|\nabla u_k\|^p_p = \|\nabla u_\infty\|^p_p, \quad g_\infty = |\nabla u_\infty|^{p-2}\nabla u_\infty.$$

Hence, $u_\infty$ is a stationary point.

To show that $u_k \to u_\infty$ in $W^{1,p}_0(\Omega)$ strongly in case $1 < p < 2$, it is enough to notice that by Lemma 3.1, one has

$$c_p \int_\Omega |\nabla (u_k - u_\infty)|^2 (|\nabla u_k| + |\nabla u_\infty|)^{p-2} dx \leq \chi_k \to 0.$$

Writing

$$\int_\Omega |\nabla (u_k - u_\infty)|^p dx$$

$$= \int_\Omega |\nabla (u_k - u_\infty)|^p (|\nabla u_k| + |\nabla u_\infty|)^{(p-2)p/2} (|\nabla u_k| + |\nabla u_\infty|)^{(2-p)p/2} dx$$

and using Hölder’s inequality with $\frac{2}{p}, \frac{2}{2-p}$, we get

$$\int_\Omega |\nabla (u_k - u_\infty)|^p dx \leq \left( \int_\Omega (|\nabla (u_k - u_\infty)|^2 (|\nabla u_k| + |\nabla u_\infty|)^{p-2} dx \right)^{\frac{p}{2}}$$

$$\times \left( \int_\Omega (|\nabla u_k| + |\nabla u_\infty|)^p dx \right)^{\frac{2-p}{2}} \leq C \chi_k \to 0.$$

This completes the proof of the lemma. $\square$
Corollary 6.1. Suppose that $E$ admits a unique global minimizer $u_\infty$ ($u_\infty$ is also a solution to the problem (4.2)) and that the initial value $u_0$ of (2.2) satisfies $E(u_0) < E(u_i)$ for any stationary point $u_i \neq u_\infty$. Then $u(\cdot, t) \to u_\infty$ in $W_0^{1,p}(\Omega)$ as $t \to +\infty$.

Proof. Recall that we have $E(u) \leq E(u_0) < E(u_i), u_i \neq u_\infty$. Then by Lemma 6.1 and (6.1), we get $E(u(t)) \to E(u_\infty)$ where $u_\infty$ is the global minimizer of $E$ and a solution of the problem (4.2). Due to the fact that $u(t)$ is uniformly bounded in $W_0^{1,p}(\Omega)$ for some subsequence, we have $u(\cdot, t_k) \rightharpoonup v_\infty$ in $W_0^{1,p}(\Omega)$. Then by the weak lower semicontinuity of $E$ (see the proof of Theorem 4.2), we obtain
\[ E(u_\infty) = \lim_{t_k \to \infty} E(u(t_k)) \geq E(v_\infty). \]
Since $u_\infty$ is a unique global minimizer of $E$, it holds that $E(u_\infty) < E(v_\infty)$ for $u_\infty \neq v_\infty$, hence $u_\infty = v_\infty$. This holds for every subsequence and the convergence is, in fact, strong (see Lemma 6.1), therefore, the result follows.

Remark 6.1. In the case where $a(s)p^{-1}$ is increasing (see (3.5) and Remark 4.1), the problem has a single stationary point and for any initial data $u(\cdot, t)$ converges to this stationary point. We refer to [9] for more asymptotic analysis.
